Deutsches Forschungszentrum für Künstliche Intelligenz

The German Research Center for Artificial Intelligence (Deutsches Forschungszentrum für Künstliche Intelligenz, DFKI) with sites in Kaiserslautern and Saarbrücken is a non-profit organization which was founded in 1988. The shareholder companies are Atlas Elektronik, Daimler-Benz, Fraunhofer Gesellschaft, GMD, IBM, Insiders, Mannesmann-Kienzle, SEMA Group, and Siemens. Research projects conducted at the DFKI are funded by the German Ministry for Research and Technology, by the shareholder companies, or by other industrial contracts.

The DFKI conducts application-oriented basic research in the field of artificial intelligence and other related subfields of computer science. The overall goal is to construct *systems with technical knowledge and common sense* which - by using AI methods - implement a problem solution for a selected application area. Currently, there are the following research areas at the DFKI:

- Intelligent Engineering Systems
- Intelligent User Interfaces
- Computer Linguistics
- Programming Systems
- Deduction and Multiagent Systems
- Document Analysis and Office Automation.

The DFKI strives at making its research results available to the scientific community. There exist many contacts to domestic and foreign research institutions, both in academy and industry. The DFKI hosts technology transfer workshops for shareholders and other interested groups in order to inform about the current state of research.

From its beginning, the DFKI has provided an attractive working environment for AI researchers from Germany and from all over the world. The goal is to have a staff of about 100 researchers at the end of the building-up phase.

September 6, 1994

Abstract

There are many forms of uncertainty, each usually again having more than one theoretical model.

Therefore, a very flexible kind of uncertainty-valued Horn clauses is introduced in RELFUN in section 1. They have a head, several premises and an uncertainty factor, which represents the uncertainty of the clause. The premises are all 'functional' in the sense that their returned value is again an uncertainty value. These premises and the uncertainty factor of an uncertainty rule become embedded into the arguments of a combination function when translating uncertainty clauses into footed clauses (non-ground, non-deterministic functions in RELFUN, which can then be compiled as usual). The combination function can be modified by the user. It may be a built-in or a user-defined function, either of which may be computed as the value of a higher-order function.

In section 2, an application of uncertainty clauses to the uncertain concept of a 'pet holder', according to German law, is described. This and another example are then fully demonstrated in appendix A. Finally, appendix B gives a listing of the complete uncertainty translator in LISP.

Contents

1 The Uncertainty Translator

This section shows a simple transformational extension of RELFUN for handling uncertainty. It is based on a proposal by Harold Boley and a lot of implementational help by Michael Sintek.

1.1 The Uncertainty Structure

There are many forms of uncertainty; for example there is vagueness (fuzziness in particular), probability, and so on [4]. Furthermore there are a lot of theoretical models to simulate the various kinds of uncertainty. To stay flexible in RELFUN [1], no special model is chosen here. It is left to the user to decide in which way he wants to describe the uncertainty of his particular problem. For this, uncertainty clauses or 'uc clauses' are introduced (we show RELFUN's two syntax styles, with the focus on the former) :

Lisp style:

```
(uc (c ..)  (ucfb1 ..)  ...  (ucfbM ..)  UC_FACTOR)
```

Prolog style:

```
c(..) :-#  ucfb1(..), ...  ,ucfbM(..), UC_FACTOR.
```

The premises `(ucfb1 ..), ... ,(ucfbM ..)` are functional and their returned values represent uncertainty factors. The explicit uncertainty factor, UC_FACTOR, stands for the uncertainty of the rule itself. Normally, and

later on in this paper, uncertainty factors will be numerical values in [0..1]. But it is also possible to think of qualitative or quantitative values in a symbolic way, for which there are two possible treatments:

- Translate symbolic values into numerical values in [0..1].
  Calculate with these numerical values in the 'normal' way.
  Retranslate numerical values into symbolic values.

- Use a special combination table for the symbolic values.

Neither the compiler nor the interpreter of normal RELFUN can directly handle uncertainty clauses. So they have to be translated into (non-ground, non-deterministic) footed clauses by embedding the premises and the uncertainty factor into a combination function, `combrule`:

Lisp style:

```
(ft (c ..)  (combrule (ucfb1 ..)  ...  (ucfbM ..)  UC_FACTOR))
```

Prolog style:

```
c(..)  :- combrule(ucfb1(..), ...  ,ucfbM(..), UC_FACTOR).
```

1.2 The Combination Function

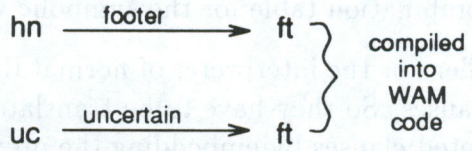
As said before, the premises have to be functional; otherwise the combination function will produce an error. Premises defined by hornish clauses have to be changed into premises defined by footed clauses with a returned value in [0..1]. This is performed by the RELFUN command `footer`, translating all hornish definitions into footed ones. `footer` expects an argument which represents the returned value of the constructed footed clauses. By default hornish clauses are understood as certain, thus their uncertainty factor is set to 1: `footer` acts like `footer 1`

The translation of uncertainty clauses into footed clauses (as described in section 1.1) is done with the function `uncertain`. Like `footer` it translates a whole database. `uncertain` expects the combination function `combrule` as argument, which may be a built-in or a user-defined function, either of which may be computed as the value of a higher-order function.

- `uncertain min` where `min` is a built-in function,
- `uncertain myrule` where `myrule` is a user-defined function,

- `uncertain (cr)` where `cr` is a (parameterless) higher-order function which returns a combination function (like a globally declared constant, this returned value can be changed easily). This can e.g. be useful in the 'test phase' of a system, when combination functions are changed several times.

Altogether, the translation yields `ft clauses`, which can then be compiled as usual:



Even more than one combination function can be used in a single database. For that, all uncertainty clauses whose returned value is calculated the same way are added to the database. This is then translated with the chosen combination function. After that the next uncertainty clauses are asserted or consulted, and a second translation with another combination function follows, etc. This is no problem because the `uncertain` command only changes the uncertainty clauses, while footed clauses stay unmodified.

Note that uncertainty facts have no premises: `(uc (c ..) UC_FACTOR)`, and no combination function is called to calculate uncertainty values: `(ft (c ..) UC_FACTOR)`.
So, if there are only uncertainty facts, it is insignificant which combination function is given to the `uncertain` command. Actually, it is possible to write uncertainty facts directly as footed facts if the returned values are understood as an uncertainty values.

We should note that our combination function combines values of the premises of a conjunction, hence could be called AND-combination function. Uncertainty systems often also permit what we may call an OR-combination function. However there is a restriction in handling uncertainty in backtracking languages like PROLOG or RELFUN: if there exists more than one solution for a query, then the individual solutions cannot easily be (OR-) combined into a final result (see the 'certainty factors' used in MYCIN). But the observation that most of these OR-combined models are mathematically inconsistent anyway [3] makes this restriction appear an advantage. Only by using `bagof` or `tupof` , is it possible to deduce all solutions in our implementation, and then compute the solution with the greatest uncertainty factor

of this collection of solutions (see function `fetch` [5] or `reduce` applied to `maxp`).

2 Example 'Pet Holder'

This section formalizes the realistic example of [2] with RELFUN's uncertainty-valued Horn clauses.

In German law, the *owner* of a pet is not always liable for the damage caused by his pet. The *pet holder*, who can be the owner, the horseman, the buyer, the finder of a deserted pet, and so on, is responsible. The problem is, that there is no *sharp* definition of 'pet holder', so a judge has to decide with common sense who is the 'pet holder'.

2.1 The Features

The term 'pet holder' is described by a set of attributes. These can be brought together in a 'deduction tree'.

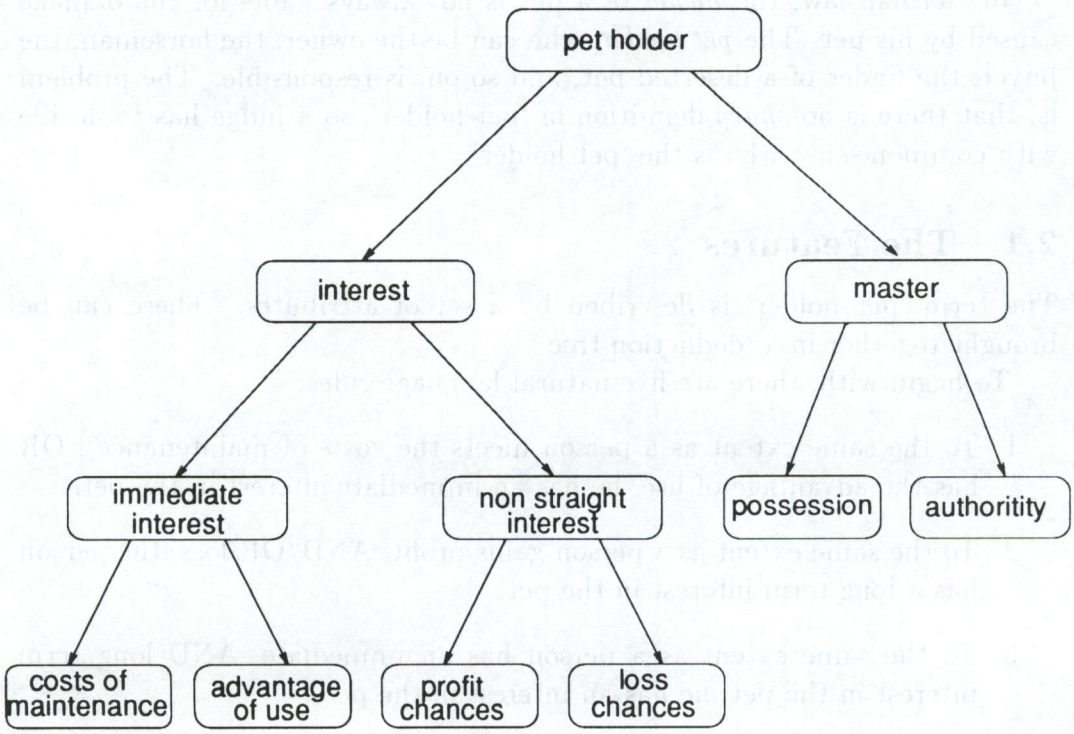
To begin with, there are five natural language rules:

1. To the same extent as a person meets the costs of maintenance , OR has the advantage of use, he has an immediate interest in the pet.
2. To the same extent as a person gains profit, AND/OR loss, the person has a long term interest in the pet.
3. To the same extent as a person has an immediate, AND long term interest in the pet, he has an interest in the pet.
4. To the same extent as a person has possession of, OR is the master of the pet, he takes responsibility for the pet.
5. To the same extent as a person has interest in, AND carries responsibility for the pet, he is a pet holder.

These features are measured in terms like:

- Costs of maintenance: shelter, food, nurture, doctor etc.
- Advantage of use: receipts of work, hiring etc.

- Profit chances: costs of procuring.
- Loss chances: initial costs, costs of education etc.
- Possession: actual power, use, shelter, nurture in the own household or farm
- Master: decision about the existence of the pet (life and use)



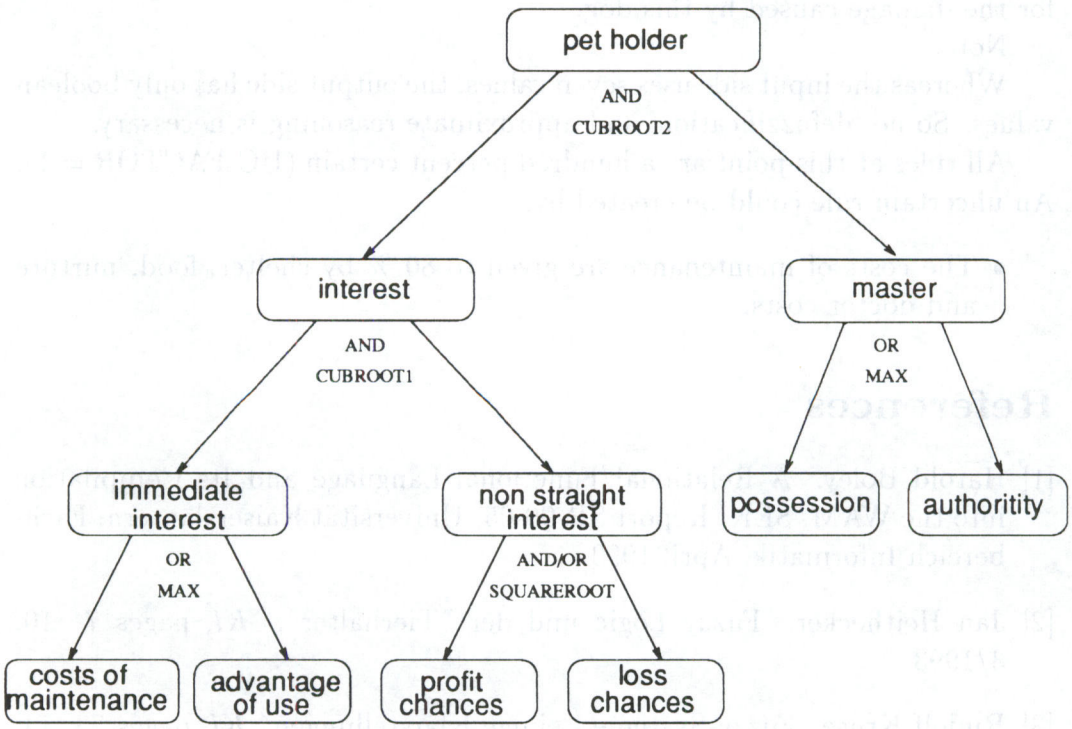
2.2 The Combination Functions

In this system more than one combination function is used. They were found by experience. It showed up, that there are four cases:

- normal AND
- normal OR
- AND with compensation

- OR with compensation

The normal AND/OR is realized with **min/max**; the AND with compensation by geometrical mean ($\sqrt[2]{x_1 \cdot \ldots \cdot x_n}$). In the case of OR with compensation it is more difficult: the attributes are in a special relation. The immediate to the long term interest are in the ratio 1 to 2 (**cubroot1** = $\sqrt[3]{x_1 \cdot x_1 \cdot x_2}$); interest to responsibility is in the inverse ratio 2 to 1 (**cubroot2** = $\sqrt[3]{x_1 \cdot x_2 \cdot x_2}$).



2.3 Finding a Pet Holder

Because it is more difficult for a human being to express something in numbers, the values for the attributes are given in natural language; they have to be translated: null = 0.01; very few = 0.1; few = 0.25; medium = 0.5; high = 0.75; very high = 0.9; total = 1. The output has to be interpreted: values over or equal to 0.5 mean 'the person is a pet holder' and values less than 0.5 mean 'the person is not a pet holder'.

E.g., it is now possible to describe the finder of a dog:

costs of maintenance	few
advantage of use	medium
profit chances	medium
loss chances	medium
possession	high
master	medium

For these values the finder of a dog is a pet holder and therefore liable for the damage caused by this dog.

Note:

Whereas the input side uses seven values, the output side has only boolean values. So no 'defuzzification' and approximate reasoning is necessary.

All rules at this point are a hundred percent certain (UC_FACTOR = 1). An uncertain rule could be created by:

- The costs of maintenance are given to 80 % by shelter, food, nurture and doctor costs.

rfi-1> ;* * * * * * * * see 'Fuzzy Reference Manual'* * * * * * * * * * *
rfi-1> ;
rfi-1> ;Fetch is called with one, three or four variabels. The required
rfi-1> ;first argument is the name of the predicate of which fetch
rfi-1> ;returns an assertion whose uncertainty factor is in the proper
rfi-1> ;range which is given through the last two arguments. It fails if
rfi-1> ;no assertion is found.If more than one solution is found, it
rfi-1> ;returns the one whose uncertainty value is closest to the lower
rfi-1> ;bound. The default range is [1,0]. Notice that you receive the
rfi-1> ;highest uncertainty value by specifying the range as
rfi-1> ;[upper, lower] and the lowest uncertainty value by
rfi-1> ;specifying it as [lower, upper]. For that you fetch the maximum
rfi-1> ;with the range [1, 0] and the minimum by [0, 1].
rfi-1> ;The second argument is the argument to which the predicate is
rfi-1> ;applied. It gets interesting if there is more than one solution
rfi-1> ;for such a query. Also here you can fetch the 'surest' or
rfi-1> ;'unsurest' solution.
rfi-1> ;The output of fetch is a list. The first element of this list
rfi-1> ;is the difference between the left bound and the uncertainty factor,
rfi-1> ;next is the uncertainty factor and last there is the binding.
